Case report

A 60-year-old man with 4-year history of slowly progressive algoparesthesias in the lower limbs, bilateral hearing loss and gait instability. No evidence of spontaneous or traumatic bleedings in the CNS, no systemic diseases.

Medical history: previous traumas (diving head concussion during childhood, severe back trauma skiing at age 20, car accident with back trauma two years before admission). Familiar history: unremarkable for neurological diseases.

Physical exam: right 6th cranial nerve palsy, bilateral hypoacusis, paretic hypertonus and diffuse brisk reflexes, bilateral Babinski’s sign, slight dysmetria, dysesthesias in lower limbs, hypopallestesia, ataxic gait, positive Romberg and pull test.

Lab exams: iron-deficient anaemia.

Audiogram: sensorineural hearing loss.

MEPs and SSEPS both delayed.

Lumbar puncture: raising of albumin, tau and p-tau levels, 22 white cells/mmc; spectrophotometry: raised levels of bilirubin.

MR imaging: linear hemosiderin deposit on the brainstem, in paravermian liquoral spaces, lateral sulci, the mesial temporal-frontal lobes and the anterior cervical and dorsal regions of the medulla. Gadolinium-enhanced suspected vascular abnormalities at D9 level.
Superficial siderosis (SS) of the central nervous system

- first described in 1908
- rare neurodegenerative condition resulting from hemosiderin deposition in the subpial layers of CNS.
- hypothesized to result from a low-volume protracted “leak” of red blood cells into the subarachnoid space.
- neurotoxic action of heme leads to Bergmann glia and microglia release of heme oxygenase-1 and ferritin (scavengers).

## Two anatomical patterns

1. **Cortical superficial siderosis (cSS):**
   - Supratentorial
   - often associated with cerebral amyloid angiopathy (CAA – older individuals)
   - transient focal neurological episodes (e.g. TIA)

2. **Infratentorial superficial siderosis (iSS):**
   - with or without supratentorial involvement
   - slowly progressive bilateral hearing loss, ataxia, and myelopathy
   - symmetrical enhancement in at least 2 of the following regions: (1) brainstem (2) cerebellum (3) spinal cord or craniocervical junction.
   - A wide range of suggested causes

### Distribution of causes

<table>
<thead>
<tr>
<th>Cause</th>
<th>cSS (n=54)</th>
<th>iSS not fulfilling diagnostic criteria (n=23)</th>
<th>Idiopathic iSS (n=48)</th>
<th>Secondary iSS (n=17)</th>

**IS IT REALLY IDIOPATHIC ???**

Proposed diagnostic algorithm for SS

1. Superficial siderosis on cranial MRI
   - Isolated supratentorial siderosis
     - Symmetrical siderosis in ≥2/3 infratentorial structures (ISS)
       - Evidence of large recent parenchymal or SAH bleed on imaging
         - No (i.e. Type 1 (classical) ISS)
           - Whole spine imaging (consider high resolution CISS or SPACE)
         - Yes
     - No
       - Investigate as appropriate (consider CAA, Aneurysm, RCVS etc.) – may include CTA/MRA/IADSA
       - Consider repeat imaging with contrast
         - No
           - Dural defect indentified
             - Yes
               - CT myelography +/- Dynamic CT myelography or direct injection into epidural collection
                 - Localised precise site of dural leak?
                   - Yes
                     - Consider surgical exploration +/- repair, or radiology-guided blood/glue patch. Deferiprone could also be considered. CSF and neuroimaging can help assess ongoing bleeding
                   - No
                     - CSF and neuroimaging can be used to assess ongoing bleeding. Chelating agent, e.g. Deferiprone, could be considered although without evidence of efficacy and with potential side effects
               - No
                 - Consider repeat myelography
   - Infratentorial +/- supratentorial siderosis

**myelography CT** (Iopamidol, 300 mg/ml)

Diffuse contrast opacification of a ventral pseudomeningocele in D2-D7 segment with tear at D7 level, and diffuse epidural abnormalities.
Thanks for the attention
